Software Architecture
an informal introduction

David Schmidt
Kansas State University

www.cis.ksu.edu/~schmidt
Outline

1. Components and connectors
2. Software architectures
3. Architectural analysis and views
4. Architectural description languages
5. Domain-specific design
6. Product lines
7. Middleware
8. Model-driven architecture
9. Aspect-oriented programming
10. Closing remarks
1. Components and connectors
Motivation for software architecture

We use already architectural idioms for describing the structure of complex software systems:

♦ “Camelot is based on the client-server model and uses remote procedure calls both locally and remotely to provide communication among applications and servers.” [Spector87]

♦ “The easiest way to make the canonical sequential compiler into a concurrent compiler is to pipeline the execution of the compiler phases over a number of processors.” [Seshadri88]

♦ “The ARC network follows the general network architecture specified by the ISO in the Open Systems Interconnection Reference Model.” [Paulk85]

Architectural description has a natural position in system design and implementation

A slide from one of David Garlan’s lectures:

There are standardized descriptions of computer hardware architectures:

- **RISC** (reduced instruction set computer)
- **pipelined architectures**
- **multi-processor architectures**

These descriptions are well understood and successful because

(i) there are a relatively small number of design components

(ii) large-scale design is achieved by replication of design elements

In contrast, software systems use a huge number of design components and scale upwards, not by replication of existing structure, but by adding more distinct design components.

Network architecture

Again, there are standardized descriptions:

♦ *star* networks

♦ *ring* networks

♦ *manhattan street* (grid) networks

The architectures are described in terms of *nodes* and *connections*. There are only a few standard topologies.

In contrast, software systems use a wide variety of topologies.
Classical architecture

The architecture of a building is described by

♦ multiple views: exterior, floor plans, plumbing/wiring, ...

♦ architectural styles: romanesque, gothic, ...

♦ style and engineering: how the choice of style influences the physical design of the building

♦ style and materials: how the choice of style influences the materials used to construct (implement) the building.

These concepts also appear in software systems: there are

(i) views: control-flow, data-flow, modular structure, behavioral requirements, ...

(ii) styles: pipe-and-filter, object-oriented, procedural, ...

(iii) engineering: modules, filters, messages, events, ...

(iv) materials: control structures, data structures, ...
A crucial motivating concept: *connectors*

The emergence of networks, client-server systems, and OO-based GUI applications led to the conclusion that *components can be connected in various ways*

Mary Shaw stressed this point:

*Figure 2: Revised architecture diagram with discrimination among connections*

Shaw’s observations

Connectors are forgotten because (it appears that) there are no codes for them.

But this is because the connectors must be coded in the same language as the components, which confuses the two forms.

Different forms of low-level connection (synchronous, asynchronous, peer-to-peer, event broadcast) are fundamentally different yet are all represented as procedure (system) calls in programming language.

Connectors can (and should?) be coded in languages different from the languages in which components are coded (e.g., unix pipes).
Shaw’s philosophy

Components — compilation units (module, data structure, filter) — are specified by interfaces.

Connectors — “hookers-up” (RPC (Remote Procedure Call), event, pipe) — mediate communications between components and are specified by protocols.

Figure 3: Gross structure of an architecture language
Interface **Central** is different from a Java-interface; it lists the “players” — inA, outB, linkC, Gorp, Thud, ... (connection points/ ports/ method invocations) — that use connectors.
The connector’s *protocol* lists

(i) the types of component interfaces it can “mediate”;
(ii) orderings and invariants of component interactions;
(iii) performance guarantees.

**Example:** Shaw’s description of a unix pipe:

*Pipe Connector*

**Informal Description:** The Unix abstraction for pipe, i.e. a bounded queue of bytes that are produced at a source and consumed at a sink. Also supports interactions between pipes and files, choosing the correct Unix implementation.

**Icon:** pipe section

**Properties:** *PipeType*, the kind of Unix pipe. Possible values Named, Unnamed

**Roles:** *Source*

**Description:** the source end of the pipe

**Accepts player types:** StreamOut of component Filter; ReadNext of component SeqFile

**Properties:** *MinConns*, minimum number of connections. Integer values, default 1  
*MaxConns*, maximum number of connections. Integer values, default 1

**Sink**

**Description:** the sink end of the pipe

**Accepts player types:** StreamIn of component Filter; WriteNext of component SeqFile

**Properties:** *MinConns*, *MaxConns*, as for *Source*

Connectors can act as

♦ **communicators**: transfer data between components (e.g., message passing, buffering)

♦ **mediators**: manage shared resource access between components (e.g., reader/writer policies, monitors, critical regions)

♦ **coordinators**: define control flow between components (e.g., synchronization (protocols) between clients and servers, event broadcast and delivery)

♦ **adaptors**: connect mismatched components (e.g., a pipe connects to a file rather than to a filter)

Perhaps you have written code for a bounded buffer or a monitor or a protocol or a shared, global variable — you have written a connector!
Connectors can facilitate

♦ **reuse:** components from one application are inserted into another, and they need not know about context in which they are connected

♦ **evolution:** components can be dynamically added and removed from connectors

♦ **heterogenity:** components that use different forms of communication can be connected together in the same system

A connector should have the ability to handle limited *mismatches* between connected components, via information reformatting, object-wrappers, and object-adaptors, such that the component is not rewritten — the connector does the reformatting, wrapping, adapting.
If connectors are crucial to systems building, why did we take so long to “discover” them? One answer is that components are “pre-packaged” to use certain connectors:

<table>
<thead>
<tr>
<th>COMPONENT TYPE</th>
<th>COMMON TYPES OF INTERACTION</th>
</tr>
</thead>
<tbody>
<tr>
<td>Module</td>
<td>Procedure call, data sharing</td>
</tr>
<tr>
<td>Object</td>
<td>Method invocation (dynamically bound procedure call)</td>
</tr>
<tr>
<td>Filter</td>
<td>Data flow</td>
</tr>
<tr>
<td>Process</td>
<td>Message passing, remote procedure call</td>
</tr>
<tr>
<td>Data file</td>
<td>Various communication protocols, synchronization</td>
</tr>
<tr>
<td>Database</td>
<td>Read, write</td>
</tr>
<tr>
<td>Document</td>
<td>Schema, query language</td>
</tr>
<tr>
<td></td>
<td>Shared representation assumptions</td>
</tr>
</tbody>
</table>

But “smart” connectors make components simpler, because the coding for interaction rests in the connectors — not the components. The philosophy, \textit{system = components + connectors} was a strong motivation for a theory of software architecture.

2. Software Architecture
What is a software architecture? (Perry and Wolf)

A software architecture consists of

1. **elements**: processing elements (“functions”), connectors (“glue” — procedure calls, messages, events, shared storage cells), data elements (what “flows” between the processing elements)

2. **form**: properties (constraints on elements and system) and relationship (configuration, topology)

3. **rationale**: philosophy and pragmatics of the system: requirements, economics, reliability, performance

There can be “views” of the architecture from the perspective of the process elements, the data, or the connectors. The views might show static and dynamic structure.

Architectural Styles (patterns)

1. **Data-flow systems**: batch sequential, pipes and filters

2. **Call-and-return systems**: main program and subroutines, hierarchical layers, object-oriented systems

3. **Virtual machines**: interpreters, rule-based systems

4. **Independent components**: communicating systems, event systems, distributed systems

5. **Repositories (data-centered systems)**: databases, blackboards

6. and there are many others, including *hybrid* architectures

The *italicized* terms are the styles (e.g., *independent components*); the roman terms are architectures (e.g., communicating system). There are specific instances of the architectures (e.g., a client-server architecture is a distributed system). But these notions are not firm!
**Data-flow systems:** Batch-sequential and Pipe-and-filter

<table>
<thead>
<tr>
<th></th>
<th><strong>Batch sequential</strong></th>
<th><strong>Pipe and filter</strong></th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Components:</strong></td>
<td>whole program</td>
<td>filter (function)</td>
</tr>
<tr>
<td><strong>Connectors:</strong></td>
<td>conventional input-output</td>
<td>pipe (data flow)</td>
</tr>
<tr>
<td><strong>Constraints:</strong></td>
<td>components execute to completion, consuming entire input, producing entire output</td>
<td>data arrives in increments to filters</td>
</tr>
</tbody>
</table>

**Examples:** Unix shells, signal processing, multi-pass compilers

**Advantages:** easy to unplug and replace filters; interactions between components easy to analyze. **Disadvantages:** interactivity with end-user severely limited; performs as quickly as slowest component.
**Call-and-return systems:** subroutine and layered

### Components:
- **Subroutine:** subroutines ("servers")
- **Layered:** functions ("servers")

### Connectors:
- **Subroutine:** parameter passing
- **Layered:** protocols

### Constraints:
- **Subroutine:** hierarchical execution and encapsulation
- **Layered:** functions within a layer invoke (API of) others at next lower layer

### Examples:
- Modular, object-oriented, N-tier systems (subroutine);
- Communication protocols, operating systems (layered)
**Advantages:** hierarchical decomposition of solution; limits range of interactions between components, simplifying correctness reasoning; each layer defines a *virtual machine*; supports portability (by replacing lowest-level components).

**Disadvantages:** components must know the identities of other components to connect to them; side effects complicate correctness reasoning (e.g., A uses C, B uses and changes C, the result is an unexpected side effect from A’s perspective; components sensitive to performance at lower levels/layers.
**Virtual machine:** *interpreter*

**Interpreter**

<table>
<thead>
<tr>
<th>Components:</th>
<th>“memories” and state-machine engine</th>
</tr>
</thead>
<tbody>
<tr>
<td>Connectors:</td>
<td>fetch and store operations</td>
</tr>
<tr>
<td>Constraints:</td>
<td>engine’s “execution cycle” controls the simulation of program’s execution</td>
</tr>
</tbody>
</table>

**Examples:** high-level programming-language interpreters, byte-code machines, virtual machines

**Advantages:** rapid prototyping  
**Disadvantages:** inefficient.
### Repositories: databases and blackboards

#### Components:
- **Database**: processes and database
- **Blackboard**: knowledge sources and blackboard

#### Connectors:
- **Database**: queries and updates
- **Blackboard**: notifications and updates

#### Constraints:
- **Database**: transactions (queries and updates) drive computation
- **Blackboard**: knowledge sources respond when enabled by the state of the blackboard. Problem is solved by cooperative computation on blackboard.

#### Examples:
- speech and pattern recognition (blackboard); syntax editors and compilers (parse tree and symbol table are repositories)
**Advantages:** easy to add new processes.

**Disadvantages:** alterations to repository affect all components.
**Independent components:** communicating processes

| Components: | processes ("tasks") |
| Connectors: | ports or buffers or RPC |
| Constraints: | processes execute in parallel and send messages (synchronously or asynchronously) |

**Example:** client-server and peer-to-peer architectures

**Advantages:** easy to add and remove processes. **Disadvantages:** difficult to reason about control flow.
Independent components: event systems

Event systems

Components: objects or processes ("threads")
Connectors: event broadcast and notification (implicit invocation)
Constraints: components "register" to receive event notification; components signal events, environment notifies registered "listeners"

Examples: GUI-based systems, debuggers, syntax-directed editors, database consistency checkers
**Advantages:** easy for new listeners to register and unregister dynamically; component reuse.

**Disadvantages:** difficult to reason about control flow and to formulate system-wide invariants of correct behavior.
Three architectures for a compiler (Garlan and Shaw)

The symbol table and tree are “shared-data connectors”

The blackboard triggers incremental checking and code generation
What do we gain from using a software architecture?

1. the architecture helps us *communicate* the system’s design to the project’s stakeholders (users, managers, implementors)

2. it helps us *analyze* design decisions

3. it helps us *reuse* concepts and components in future systems
4. Architecture Description Languages
A language for connectors: UniCon

Shaw developed a language, *UniCon* (*Universal Connector Language*), for describing connectors and components.

**Components** are specified by *interfaces*, which include

(i) type;
(ii) attributes with values that specialize the type;
(iii) *players*, which are the component’s connection points. Each player is itself typed.

**Connectors** are specified by *protocols*; they have

(i) type;
(ii) specific properties that specialize the type;
(iii) *roles* that the connector uses to mediate (make) communication between components.
Graphical depiction of an assembly of three components and four connectors:

A development tool helps the designer draw the configuration and map it to coding.

uses statements instantiate the parts composed

connect statements state how players satisfy roles

bind statements map the external interface to the internal configuration
Connectors described in UniCon:

♦ data-flow connectors (pipe)

♦ procedural connectors (procedure call, remote procedure call): pass control

♦ data-sharing connectors (data access): export and import data

♦ resource-contention connectors (RT scheduler): competition for resources

♦ aggregate connectors (PL bundler): compound connections
Pipe Connector

Informal Description: The Unix abstraction for pipe, i.e. a bounded queue of bytes that are produced at a source and consumed at a sink. Also supports interactions between pipes and files, choosing the correct Unix implementation.

Icon: pipe section

Properties: PipeType, the kind of Unix pipe. Possible values Named, Unnamed

Roles: Source

Description: the source end of the pipe
Accepts player types: StreamOut of component Filter; ReadNext of component SeqFile
Properties: MinConns, minimum number of connections. Integer values, default 1
MaxConns, maximum number of connections. Integer values, default 1

Sink

Description: the sink end of the pipe
Accepts player types: StreamIn of component Filter; WriteNext of component SeqFile
Properties: MinConns, MaxConns, as for Source
**ProcedureCall Connector**

**Informal Description:** The architectural abstraction corresponding to the procedure call of standard programming languages. Requires signatures (eventually pre/post conditions) in the RoutineDef and RoutineCall players to match; if they don’t, requests remediation. Supports renaming.

**Icon:** blunt arrowhead

**Roles:** *Definer*

- **Description:** role played by the procedure definition
- **Accepts player types:** RoutineDef of component Computation or Module
- **Properties:** MinConns, minimum number of definitions allowed. Integer, must be 1
  MaxConns, maximum number of definitions allowed. Integer, must be 1

**Caller**

- **Description:** the role played by the procedure call
- **Accepts player types:** RoutineCall of component Computation or Module
- **Properties:** MinConns, minimum number of callers allowed. Integer, default 1
  MaxConns, maximum number of callers allowed. Integer, default many

**RemoteProcCall Connector**

**Informal Description:** The abstraction for the remote procedure call facility supplied by the operating system. Requires signatures and eventually pre/post conditions in the RPCDef and RPCCall players to match. RemoteProcCall connectors require much more UniCon support than ProcedureCall connectors, as they must establish communication paths between processes.

**Icon:** bordered blunt arrowhead

**Roles:** *Definer*

- **Description:** role played by the procedure definition
- **Accepts player types:** RPCDef of component Process or SchedProcess
- **Properties:** MinConns, MaxConns, as for ProcedureCall

**Caller**

- **Description:** the role played by the procedure call
- **Accepts player types:** RPCCall of component Process or SchedProcess
- **Properties:** MinConns, MaxConns, as for ProcedureCall
**DataAccess Connector**

**Informal Description:** The architectural abstraction corresponding to imported and exported data of conventional programming languages.

**Icon:** triangle

**Roles:** Definer, essentially similar to Definer of ProcedureCall
User, essentially similar to Caller of ProcedureCall

---

**RTScheduler Connector**

**Informal Description:** Mediates competition for processor resources among a set of real-time processes (requires an operating system with appropriate real-time capabilities).

**Icon:** stopwatch

**Properties:** Algorithm, the scheduling discipline. Possible values: RateMonotonic, TimeSharing, EarliestDeadline, DeadlineMonotonic, RoundRobinFixPriority, FIFOUnFixPriority

**Processor**, the name of the processor on which this set of processes will run

**Trace**, a path through the real-time code and the trigger that invokes it

**Roles:** Load

**Description:** the role played by a real-time load on a processor

**Accepts player types:** RTLoad of component SchedProcess

**Properties:** MinConns, minimum number of competing processes. Integer, default 2

MaxConns, maximum number of competing processes. Integer, default many
**PLBundler Connector**

**Informal Description:** A composite abstraction for matching definitions and uses of a collection of procedures and data. It allows multiple procedure and data definitions and uses to be matched with a single abstraction. Supports renaming.

**Icon:** chain links

**Properties:** Match, the correspondences between individual definitions in the bundles. Values are sets of pairs of names.

**Roles:** Participant

- **Description:** a set of definitions and uses to take part in the linkage
- **Accepts player types:** PLBundle of component Computation, Module, or SharedData
- **Properties:** MinConns, minimum number of bundles to match. Integer, default 2
  MaxConns, maximum number of bundles to match. Integer, default many
Garlan and Allen developed Wright to specify protocols. Here is a single-client/single-server example:

```
System SimpleExample
  component Server =
    port provide [provide protocol]
    spec [Server specification]
  component Client =
    port request [request protocol]
    spec [Client specification]
  connector C-S-connector =
    role client [client protocol]
    role server [server protocol]
    glue [glue protocol]
end SimpleExample.
```

The protocols are specified with Hoare’s CSP (Communicating Sequential Processes) algebra.
connector C-S-connector =
    role Client = (request!x → result?y → Client) ⊕ §
    role Server = (invoke?x → return!y → Server) ⌋ §
    glue = (Client.request?x → Server.invoke!x → Server.return?y → Client.result!y → glue) ⌋ §

The glue protocol synchronizes the Client and Server roles:

\[
\begin{align*}
\text{Client} & \parallel \text{Server} \parallel \text{glue} \\
\Rightarrow & \text{result?y} \rightarrow \text{Client} \parallel \text{Server} \parallel \text{Server.invoke!x} \rightarrow \ldots \\
\Rightarrow & \text{result?y} \rightarrow \text{Client} \parallel \text{return!y} \rightarrow \text{Server} \parallel \\
& \text{Server.return?y} \rightarrow \ldots \\
\Rightarrow & \ldots \Rightarrow \text{Client} \parallel \text{Server} \parallel \text{glue}
\end{align*}
\]
Forms of CSP processes:

♦ prefixing:  
\[ e \rightarrow P \]
\[ \text{plusOne} \ x \rightarrow \text{return}!x + 1 \rightarrow \cdots || \text{plusOne}!2 \rightarrow \text{return}!y \rightarrow \cdots \]
\[ \Rightarrow \text{return}!2 + 1 \rightarrow \cdots || \text{return}!y \rightarrow \cdots \]

♦ external choice:  
\[ P \parallel Q \]
\[ \text{plusOne} \ x \rightarrow \cdots \parallel \text{plusTwo} \ x \rightarrow \cdots x + 2 \cdots || \text{plusTwo}!5 \rightarrow \cdots \]
\[ \Rightarrow \cdots 5 + 2 \cdots || \cdots \]

♦ internal choice:  
\[ P \sqcap Q \]
\[ \text{plusOne} \ x \rightarrow \cdots \parallel \text{plusOne}!5 \rightarrow \cdots \sqcap \text{plusTwo}!5 \rightarrow \cdots \]
\[ \Rightarrow \text{plusOne} \ x \rightarrow \cdots \parallel \text{plusTwo}!5 \rightarrow \cdots \]

♦ parallel composition:  
\[ P || Q \]

♦ halt:  
\[ § \]

♦ (tail) recursion:  
\[ p = \cdots p \] (More formally, \( \mu z. P \), where \( z \) may occur free in \( P \).)
A pipe protocol in Wright

```
connector Pipe =
    role Writer = write→Writer □ close→ §
    role Reader = let ExitOnly = close→ §
        in let DoRead = (read→Reader □ read-eof→ExitOnly)
        in DoRead □ ExitOnly
    glue = let ReadOnly = Reader.read→ReadOnly
        in let WriteOnly = Writer.write→WriteOnly □ Writer.close→ §
        in Writer.write→glue □ Reader.read→glue
            in Writer.close→ReadOnly □ Reader.close→WriteOnly
```

**C2: an N-tier framework and language**

Developed at Univ. of California, Irvine, Institute of Software Research: [http://www.isr.uci.edu/architecture/c2.html](http://www.isr.uci.edu/architecture/c2.html)

---

Diagrams are from Medvidovic’s course,

Graphics Binding

CS 612: Software Architectures  February 9, 1999
Here is a **C2SADEL** description of the video game’s “Well” component:

```plaintext
component WellADT is subtype Matrix (beh) {
    state {
        capacity : Integer;
        num_tiles : Integer;
        well_at : Integer -> GSColor;
    }
    invariant {
        (num_tiles [\geq] 0) \and (num_tiles [\leq] capacity);
    }
    interface {
        prov gt1: GetTile (location : Integer) : Color;
        prov gt2: GetTile (i : Natural) : GSColor;
    }
    operations {
        prov tileget: {
            let pos : Integer;
            pre (pos [\geq] 0) \and (pos [\leq] num_tiles);
            post \result = well_at(pos) \and ~num_tiles = num_tiles - 1;
        }
    }
    map {
        gt1 -> tileget (location -> pos);
        gt2 -> tileget (i -> pos);
    }
}
```

And here is a description of a connector and part of the configuration:

```plaintext
connector BroadcastConn is {
    message_filter no_filtering;
}

architectural_topology {
    component_instances {
        Well : WellADT;
        WellArt : WellArtist;
        MatchLogic : TileMatchLogic;
    }
    connector_instances {
        ADTConn : BroadcastConn;
        ArtConn : BroadcastConn;
    }
    connections {
        connector ADTConn {
            top Well;
            bottom MatchLogic, ArtConn;
        }
        connector ArtConn {
            top ADTConn;
            bottom WellArt;
        }
    }
}
```
ArchJava: Java extended with Unicon features

- Each component (class) has its own interfaces (*ports*) that list which methods it requires and provides.

- Connectors are coded as classes, too, and extend the basic classes, Connector, Port, Method, etc.

- The ArchJava run-time platform includes a run-time type checker that enforces correctness of run-time connections (e.g., RPC, TCP).

- There is an open-source implementation and Eclipse plug-in.

- www.archjava.org
package pos;

From K. M. Hansen, www.daimi.dk/~marius/teaching/ATiSA2005
public class TCPConnector extends Connector {
    // data members
    protected TCPEndpoint endpoint;
    // public interface
    public TCPConnector(InetAddress host, int prt, String objName) throws IOException {
        endpoint = new TCPEndpoint(this, host, prt, objName);
    }

    public Object invoke(Call call) throws Throwable {
        Method meth = call.getMethod();
        return endpoint.sendMethod(meth.getName(), meth.getParameterTypes(), call.getArguments());
    }

    public static void registerObject(Object o, int prt, String objName) throws IOException {
        TCPDaemon.createDaemon(prt).register(objName, o);
    }
    // interface used by TCPDaemon
    TCPConnector(TCPEndpoint endpoint, Object receiver, String portName) {
        super(new Object[] { receiver }, new String[] { portName });
        this.endpoint = endpoint;
        endpoint.setConnector(this);
    }

    Object invokeLocalMethod(String name, Type parameterTypes[], Object arguments[]) throws Throwable {
        // find method with parameters that match parameterTypes
        Method meth = findMethod(name, parameterTypes);
        return meth.invoke(arguments);
    }
}
So, what is an architectural description language?

It is a notation (linear or graphical) for specifying an architecture.

It should specify

♦ **structure**: components (interfaces), connectors (protocols), configuration (both static and dynamic structure)

♦ **behavior**: semantical properties of individual components and connectors, patterns of acceptable communication, global invariants,

♦ **design patterns**: global constraints that support correctness-reasoning techniques, design- and run-time tool support, and implementation.

But it is difficult to design a *general-purpose* architectural description language that is *elegant*, *expressive*, and *useful*. 
5. Domain-specific design
Domain-specific design

If the problem domain is a standard one (e.g., flight-control or telecommunications or banking), then there are precedents to follow.

A Domain-Specific Software Architecture has

- a **domain**: defines the problem area domain concepts and terminology; customer requirements; scenarios; configuration models (entity-relationship, data flow, etc.)

- **reference requirements**: *features* that restrict solutions to fit the domain. (“Features” are studied shortly.) Also: platform, language, user interface, security, performance

- a **reference architecture**

- a **supporting environment/infrastructure**: tools for modelling, design, implementation, evaluation; run-time platform

- a **process** or **methodology** to implement the reference architecture and evaluate it.
Avionics DSSA

- Avionics Domain Application Generation Environment
- Layered reference architecture
  - subsystems decomposed into primitive components with standardized interfaces
  - over 40 different realms with over 350 distinct components
    - $\text{realm} \equiv \{ x : \text{component} \mid (\forall i,j)(x_i.\text{interface} = x_j.\text{interface}) \}$
- ADAGE reference architecture model:
  - reference architecture is defined by component realms and domain-specific composition constraints
  - even simple avionics systems often require over 50 distinct components stacked 15 layers deep

from Medvidovic's course, [http://sunset.usc.edu/classes/cs578_2002](http://sunset.usc.edu/classes/cs578_2002)
Domain-specific (modelling) language (DSL)

is a modelling language specialized to a specific problem domain, e.g., telecommunications, banking, transportation.

*We use a DSL to describe a problem and its solution in concepts familiar to people who work in the domain.*

It might define (entity-relationship) models, ontologies (class hierarchies), scenarios, architectures, and implementations.

**Example: a DSL for sensor-alarm networks:** *domains:* sites (building, floor, hallway, room), devices (alarm, movement detector, camera, badge), people (employee, guard, police, intruder). Domain elements have *features/attributes* and *operations*. *Actions* can be by initiated by *events* — “when a movement detector detects an intruder in a room, it generates a movement-event for a camera and sends a message to a guard....”

When a DSL can generate computer implementations, it is a *domain-specific programming language.*
Domain-specific programming language

In the Unix world, these are “little languages” or “mini-languages,” designed to solve a specific class of problems. Examples are awk, make, lex, yacc, ps, and Glade (for GUI-building in X).

Other examples are Excel, HTML, XML, SQL, regular-expression notation and BNF. These are called top-down DSLs, because they are designed to implement domain concepts and nothing more. Non-programmers can use a top-down DSL to write solutions.

The bottom-up approach, called embedded or in-language DSL, starts with a dynamic-data-structure language, like Scheme or Perl or Python, and adds libraries (modules) of functions that encode domain-concepts-as-code, thus “building the language upwards towards the problem to be solved.” Experienced programmers use bottom-up DSLs to program solutions.
Tradeoffs in using (top-down) DSLs

✔ non-programmers can discuss and use the DSL

✔ the DSL supports patterns of design, implementation, and optimization

✔ fast development

✘ staff must be trained to use the DSL

✘ interaction of DSL-generated software with other software components can be difficult

✘ there is high cost in developing and maintaining a DSL

6. Software product lines
A software product line is also called a *software system family* — a collection of software products that share an architecture and components, constructed by a product line. They are inspired by the products produced by industrial assembly lines, e.g., automobiles.

The CMU Software Engineering Institute definition:

*A product line is a set of software intensive systems that*

(i) share a common set of features,

(ii) satisfy the needs of a particular mission, and

(iii) are developed from a set of core assets in a prescribed way.

**Key issues:**

*variability:* Can we state precisely the products’ variations (*features*)?

*guidance:* Is there a precise recipe that guides feature selection and product assembly?

Reference: [www.softwareproductlines.com](http://www.softwareproductlines.com)
An example product line: Cummins Corporation

produces diesel engines for trucks and heavy machinery. An engine controller has 100K-200K lines-of-code. At level of 12 engine “builds,” company switched to a product line approach:

1. defined engine controller domain
2. defined a reference architecture
3. built reusable components
4. required all teams to follow product line approach

Cummins now produces 20 basic “builds” — 1000 products total; development time dropped from 250 person/months to < 10. A new controller consists of 75% reused software.

Features and feature diagrams

are a development tool for domain-specific architectures and product lines. They help define a domain’s reference requirements and guide implementations of instances of the reference architecture.

A *feature* is merely a property of the domain. (Example: the features/options/choices of an automobile that you order from the factory.)

A *feature diagram* displays the features and guides a user in choosing features for the solution to a domain problem.

It is a form of decision tree with *and-or-xor* branching, and its hierarchy reflects dependencies of features as well as modification costs.
Feature diagram for assembling automobiles

Filled circles label required features; unfilled circles label optional ones. Filled arcs label xor-choices; unfilled arcs label or-choices (where at least one choice is selected).

Here is one possible outcome of “executing” the feature diagram:
Feature diagrams work well for configuring generic data structures:

```
        list
       /   
-morphism mono- poly- ownership copy reference
```

Compare the diagram to the typical class-library representation of a generic list structure.

An advantage of a feature-diagram construction of a list structure over a class-library construction is that the former can generate a smaller, more efficient list structure, customized to exactly the choices of the client.
Feature diagrams are useful for both *constraining* as well as *generating* an architecture: the feature requirements are displayed in a feature diagram, which guides the user to generating the desired instance of the reference architecture.

Feature diagrams are an attempt at making software assembly appear similar to assembly of mass-produced products like automobiles.

In particular, feature diagrams encourage the use of *standardized, parameterized, reusable software components*.

Feature diagrams might be implemented by a tool that selects components according to feature selection. Or, they might be implemented within the structure of a *domain-specific programming language* whose programs select and assemble features.

Generative programming

is the name given to the application of programs that generate other programs (cf. “automatic programming” in the 1950s). A compiler is of course a generating program, but so are feature-diagram-driven frameworks, partial evaluators, and some development environments (e.g., for Java beans).

Figure 1: Technology spectrum for architecture selection and creation

Reference: Coming attractions in software architecture, P. Clements. CMU/SEI-96-TR-008.
Generative programming is motivated by the belief that conventional software production methods (even those based on “object-oriented” methodologies) will never support component reuse:

![Diagram of software architecture](image)

One solution is to understand a software system as a customized product, produced by generative programming, from a product line.

10. Final Remarks
<table>
<thead>
<tr>
<th>Academia</th>
<th>Industry</th>

<th><strong>Academia</strong></th>
<th><strong>Industry</strong></th>
</tr>
</thead>
<tbody>
<tr>
<td>Reusable components are black-box entities.</td>
<td>Components are large pieces of software (sometimes more than 80 KLOC) with a complex internal structure and no enforced encapsulation boundary, e.g., object-oriented frameworks.</td>
</tr>
<tr>
<td>Components have narrow interface through a single point of access.</td>
<td>The component interface is provided through entities, e.g., classes in the component. These interface entities have no explicit differences to non-interface entities.</td>
</tr>
<tr>
<td>Components have few and explicitly defined variation points that are configured during instantiation.</td>
<td>Variation is implemented through configuration and specialization or replacement of entities in the component. Sometimes multiple implementations (versions) of components exist to cover variation requirements.</td>
</tr>
<tr>
<td>Components implement standardized interfaces and can be traded on component markets.</td>
<td>Components are primarily developed internally. Externally developed components go through considerable (source code) adaptation to match the product-line architecture requirements.</td>
</tr>
<tr>
<td>Focus is on component functionality and on the formal verification of functionality.</td>
<td>Functionality and quality attributes, e.g. performance, reliability, code size, reusability and maintainability, have equal importance.</td>
</tr>
